Figure S1: Partial charge distribution $\rho_{vc}$ of (a) the threefold degenerate $t_{1u}$ LUMO of C$_{60}$, (b) the fivefold degenerate $h_u$ HOMO of C$_{60}$, and (c) the partly occupied doubly degenerate state of La@C$_{60}$ at the Fermi level. The isosurface value of $\rho_{vc}$ plotted is 0.003 e/Å$^3$.

Origin of superconductivity in alkali-based M$_3$C$_{60}$ solids

After a long scientific discussion following the observation of superconductivity in K$_3$C$_{60}$ and other alkali-based M$_3$C$_{60}$ intercalation compounds, the following interpretation of this phenomenon has emerged and is now accepted by the scientific community. (i) Alkali-based M$_3$C$_{60}$ solids are superconductors described well by the BCS theory. The electron-phonon coupling results from a dynamical Jahn-Teller effect on individual C$_{60}$ cages, made possible by retardation, and is confirmed by the isotope effect observed when substituting pure $^{12}$C$_{60}$ by pure $^{13}$C$_{60}$ fullerenes. (ii) The dominating role of the intercalated alkali atoms is to partly fill the $t_{1u}$ LUMO of C$_{60}$ that broadens to a narrow band in the M$_3$C$_{60}$ molecular solid. (iii) Changes in $T_c$ are well described by the changing electron-phonon coupling constant $\lambda = VN(E_F)$ in the McMillan equation. Since the on-ball Bardeen-Pines interaction $V$ does not change, $\lambda$ is proportional to the electronic density of states at the Fermi level $N(E_F)$, which is roughly inversely proportional to the width of the $t_{1u}$-derived band. Substituting intercalated K atoms by heavier alkali atoms M leads to an increase of the C$_{60}$−C$_{60}$ separation, thus reducing the width of the $t_{1u}$ band and consequently increasing the electron-phonon coupling constant $\lambda$. We should note that the range of lattice constants allowing superconductivity is limited. Changing the lattice constant changes the inter-ball hopping integral $t$, while not affecting the on-ball Coulomb integral $U$. The $U/t$ ratio increases with increasing lattice constant and, beyond a critical value, changes doped C$_{60}$ from a metal to a Mott-Hubbard insulator$^{1,2}$.

Frontier states in C$_{60}$ and La@C$_{60}$ molecules

To better understand the effect of the encapsulated La atom on the electronic structure of the La@C$_{60}$ molecule, we calculated the partial charge density of the LUMO and the HOMO of C$_{60}$ as well as that of the doubly degenerate
Figure S2: Ten different La@C$_{60}$(CF$_3$)$_2$ isomers functionalized with 2 CF$_3$ radicals. The subfigures display the following isomers: (a) 2(1), (b) 2(2), (c) 2(3), (d) 2(4), (e) 2(5), (f) 2(6), (g) 2(7), (h) 2(8), (i) 2(9), (j) 2(10). The top panels show the ball-and-stick models of the structures, followed by the DFT-PBE relative total energy values $\Delta E$ with respect to the most stable isomer. The bottom panels show the Schlegel diagrams of functionalized C$_{60}$ molecules, with the trifluoromethyl sites indicated by the red dots.

level of La@C$_{60}$ at the Fermi level. The corresponding results are presented in Figure S1. As mentioned in the main manuscript, there is an $\approx$1.6 eV wide gap between the threefold degenerate $t_{1u}$ LUMO and the fivefold degenerate $h_u$ HOMO of the pristine C$_{60}$ molecule. In La@C$_{60}$, on the other hand, the partly occupied, doubly degenerate state at $E_F$, which originally belonged to the threefold degenerate LUMO of C$_{60}$, defines the Fermi level and provides this molecule with a “metallic” character.

The partial charge densities of the LUMO state in Figure S1(a) and the HOMO of C$_{60}$ in Figure S1(b) show that both states are mainly associated with the p$_\perp$ orbitals of C atoms and are equally distributed across all atoms of the pristine fullerene molecule. The partial charge density of the partly occupied state at the Fermi level of the endohedrally doped La@C$_{60}$ molecule, shown in Figure S1(c), resembles that of the $t_{1u}$ LUMO of C$_{60}$. It consists mostly of p$_\perp$ orbitals of C atoms, with only a small contribution from the enclosed La atom, consistent with our claim that the main role of La is to transfer extra electrons to the $\pi$ electron network on the C$_{60}$ cage. We note that the charge in the HOMO/LUMO level of La@C$_{60}$ is not distributed evenly across the C$_{60}$ cage. This finding agrees with our Bader charge analysis and is particularly noticeable in Figure S1(c). It can be explained by the positively charged La atom gaining energetically from an off-center displacement, caused by the image-charge interaction, which skews the electron distribution.
on the cage towards the encapsulated La atom. Very similar changes occur in the $t_{1g}$-derived state of $C_{60}$ that acquires a net charge from nearby $exo$-hedral alkali atoms M in the superconducting $M_3C_{60}$ solid.

Equilibrium structure and stability of different $La@C_{60}(CF_3)_m$ isomers

As mentioned in the main manuscript, the endohedral fullerene $La@C_{60}$ can be functionalized by CF$_3$ radicals that attach on-top of C atoms and can be arranged in different ways across the $C_{60}$ cage. To identify the most stable $La@C_{60}(CF_3)_m$ geometry, we compared the total energies of different regioisomers containing $m$ trifluoromethyl radicals. Our results for $m = 2, 3, 4$ and 5 are shown in Figures S2, S3, S4 and S5, respectively. Each isomer is identified as $m(i)$, where $m$ denotes the number of CF$_3$ radicals and $i$ is the assigned isomer number.

Our results for 10 different arrangement of $m = 2$ CF$_3$ radicals adsorbed on the $C_{60}$ cage are shown in Figure S2. For each regioisomer, we display the optimum geometry, the corresponding Schlegel diagram and relative energy with respect to the most stable $La@C_{60}(CF_3)_m$ structure. The most stable $m = 2$ regioisomer in the para (third neighbor) positions on a single hexagon on the $C_{60}$ surface and the molecule has a $C_{2v}$ symmetry. Other arrangements penalized energetically up to $\lesssim 1$ eV, with the least stable arrangement containing CF$_3$ radicals in adjacent sites. Comparing the relative energies, we found that CF$_3$ radicals prefer to be close, but not too close on the $C_{60}$ surface.

As seen in Figure S3, a very similar picture emerges for $m = 3$ CF$_3$ radicals adsorbed on $La@C_{60}$. Comparing the structure of six different isomers in ball-and-stick models as well as Schlegel diagrams, we found that the most stable isomer, shown in Figure S3(a), contains all CF$_3$ radicals in para (third neighbor) positions on adjacent hexagonal rings on the $C_{60}$ surface, resulting in a mirror symmetry. The second most stable isomer, shown in Figure S3(f), contains CF$_3$ radicals separated by 5 neighbor distances, is only $\approx 0.1$ eV less stable and has a $C_3$ symmetry. Even though nearest-neighbor arrangements of CF$_3$ radicals were not considered, other structural candidates incurred an energy penalty of up to $\lesssim 1.3$ eV with respect to the most stable isomer.

The structural paradigm changes for $m = 4$ CF$_3$ radicals adsorbed on the $La@C_{60}$ metallofullerene. Among the 10 regioisomers displayed in Figure S4, the most stable structure, shown in Figure S4(a), contains two pairs of CF$_3$ radicals in para-arrangement on hexagonal rings that are separated by half the circumference of the $C_{60}$ molecule. The arrangement in Figure S4(e), with all $m = 4$ CF$_3$ radicals in para arrangement on adjacent hexagonal rings, is energetically the second-best isomer, with its energy only 0.051 eV higher than the most stable structure. The most stable isomer has a $C_{2v}$ symmetry and the second most stable isomer only a mirror symmetry.

The structural paradigm for $La@C_{60}(CF_3)_m$ regioisomers with $m = 5$ CF$_3$ radicals is similar to the $m = 4$ case. Ten regioisomers are presented in Figure S5. The most stable of them, shown in Figure S5(a), contains 4 CF$_3$ radicals in para arrangement on three adjacent hexagonal rings. The last radical is separated by 4 neighbor distances from the closest CF$_3$ radical. It is also possible to arrange all five CF$_3$ radicals in para positions on four adjacent hexagonal rings. As seen in Figure S5(b), this highly symmetric regioisomer is less stable by $\lesssim 0.9$ eV than the most stable structure.
