PROBLEM. An angular part of the wave function of a particle is

$$
\begin{equation*}
\psi=A \sin ^{2} \theta . \tag{1}
\end{equation*}
$$

Find the possible values of $l$ and $m$ in this state and their probabilities.

## SOLUTION.

The absence of the $\phi$-dependence shows that only $m=0$ is possible. Because of parity, we can have only even $l$, and since this is a polynomial of the second order in $\cos \theta$, the allowed values are $l=0$ and $l=2$. Therefore we have a superposition of $Y_{00}$ and $Y_{20}$, or $P_{0}=1$ and $P_{2}=(3 / 2) \cos ^{2} \theta-(1 / 2)$,

$$
\begin{equation*}
\psi=A\left[1-\cos ^{2} \theta\right]=A \cdot \frac{2}{3}\left(P_{0}-P_{2}\right)=\frac{2}{3} A \sqrt{4 \pi}\left(Y_{00}-\frac{1}{\sqrt{5}} Y_{20}\right) \tag{2}
\end{equation*}
$$

¿From the weights of the relative components of the orthonormalized functions $Y_{00}$ and $Y_{20}$ we find the probabilities $w_{2}$ of $l=2$ and $w_{0}$ of $l=0$ :

$$
\begin{equation*}
w_{2}=\frac{1}{6}, \quad w_{0}=\frac{5}{6} . \tag{3}
\end{equation*}
$$
