# PHY-852: QUANTUM MECHANICS II <br> Quiz 4 <br> April 2002 

PROBLEM. Electrons in an atom are in the stationary state with total angular momentum $\mathbf{J}$. A nucleus of the atom has its own angular momentum $\mathbf{I}$. The hyperfine interaction between the magnetic moments of the electrons and the nucleus is proportional to the scalar product of the angular momenta,

$$
\begin{equation*}
V_{h . f . s .}=A(\mathbf{J} \cdot \mathbf{I}) . \tag{1}
\end{equation*}
$$

a. Which of the following quantities are conserved by this interaction: components of the vectors $\mathbf{J}, \mathbf{I}, \mathbf{J} \pm \mathbf{I}$, their squares $\mathbf{J}^{2}, \mathbf{I}^{2},(\mathbf{J} \pm \mathbf{I})^{2}$ ?
$b$. For given absolute values of $J$ and $I$, what splitting of original atomic levels is produced by this interaction (how many split levels and what is the energy spacing between them)?

SOLUTION. a. The total angular momentum of the atom

$$
\begin{equation*}
\mathbf{F}=\mathbf{J}+\mathbf{I} \tag{2}
\end{equation*}
$$

is the only vector whose components are constants of motion. But all squares are conserved.
b. The split levels carry the possible values of $F$ from $|J-I|$ to $J+I$. The number of split levels is $2 J_{<}+1$, where $J_{<}$is the smaller of $J$ and $I$. The shift of the level with the total momentum $F$ is

$$
\begin{equation*}
\delta E(F)=\frac{A}{2}[F(F+1)-J(J+1)-I(I+1)] . \tag{3}
\end{equation*}
$$

The spacing between the adjacent split levels,

$$
\begin{equation*}
\delta E(F)-\delta E(F-1)=\frac{A}{2}[F(F+1)-(F-1) F]=A F . \tag{4}
\end{equation*}
$$

is linear in $F$.
