

## Atoms Absorb & Emit Light–January 28

- First test is next Wed
  - Covers atoms & light.
  - Does not cover telescopes (Mon).
  - Practice test on angel.
  - “Missouri Club” (Show me)
    - Mon, 31 Jan, 7:00-8:00pm, 1415 BPS (next door)
- Clicker scores
  - What counts are the scores starting with 4th classes.
  - Absent means you did not click for that day. If you did not click during classes 1-3, your grade is not hurt.
  - Ignored questions are not averaged properly. Will be fixed soon.
- **Atoms emit and absorb light**

## Black-Body Spectrum

[Fig. 5.10]

• Peak wavelength given by **Wien's Law**.

$$\lambda_{\max} = 0.0027 \text{ m} \cdot \text{K} / T$$

• hotter objects have peak at smaller  $\lambda$ .

• Total energy emitted per s *per unit surface area* is given by **Steffan-Boltzmann Law**:

$$E = \sigma T^4$$

• Increase with temperature is very steep:  
factor of 2 for a factor of 1.2 in temperature

1. There is light in a dark room. The plausible reason is
  - a. It is impossible to cover the windows completely
  - b. My eyes see blotchy light in a dark room
  - c. Everything in the room emits infrared light, which our eyes cannot see.
2. A hot object emits more infrared radiation than a cool object. An example of this is
  - a. Q & S
  - b. P & R
  - c. R & S
  - d. R & Q
3. S1: A hot star always emits more light than a cool star. S2: The sun is pretty bright at infrared wavelengths of 10,000nm.
  - a. S1 is true; S2 is true.
  - b. S1 is true; S2 is false.
  - c. S1 is false; S2 is true.
  - d. S1 is false; S2 is false.

## Light is the atom's fingerprint –Spectroscopy

- **Spectrograph**. Instrument that measures how bright the light is at each individual wavelength.
  - Prism spreads light by color
  - Grating does the same
- Each element emits a unique set of spectral lines, its fingerprint
  - A spectrum of starlight reveals what elements are in the star.

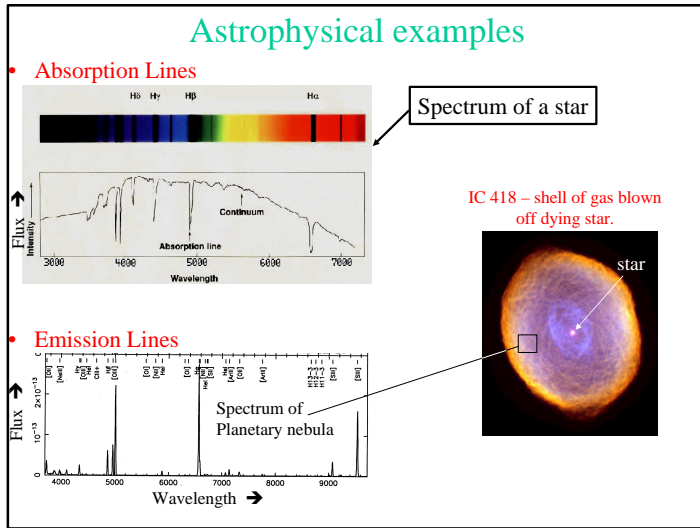

Detector measures brightness of light at each point in vertical direction.

- ### Questions on readings
- Atoms emit & absorb light
    - Which is an example of an atom
      - Water
      - Air
      - Carbon dioxide
      - Helium
    - When an oxygen atom absorbs light
      - One of its electrons gains energy
      - One of its protons gain energy
      - One of its electrons loses energy
      - One of its protons loses energy

### Atoms

Ten million atoms could fit end to end across this dot.

The nucleus is nearly 100,000 times smaller than the atom but contains nearly all of its mass.

Atom: Electrons are "smeared out" in a cloud around the nucleus.

Nucleus: Contains positively charged protons (red) and neutral neutrons (gray).

10<sup>-10</sup> meter

[Fig. 5.4]

- Electrons in orbit around nucleus.
- Nucleus =
  - Protons (+ charge)
  - Neutrons (no charge)
- Different chemical elements distinguished by different numbers of protons.

atomic number = number of protons  
atomic mass number = number of protons + neutrons

<p><b>Hydrogen (<sup>1</sup>H)</b></p> <p>atomic number = 1 atomic mass number = 1 (1 electron)</p>	<p><b>Helium (<sup>4</sup>He)</b></p> <p>atomic number = 2 atomic mass number = 4 (2 electrons)</p>	<p><b>Carbon (<sup>12</sup>C)</b></p> <p>atomic number = 6 atomic mass number = 12 (6 electrons)</p>
---	---	--

The number of electrons in a neutral atom equals its atomic number.

Different isotopes of a given element contain the same number of protons but different numbers of neutrons.		
<p><b>carbon-12</b></p> <p><sup>12</sup>C (6 protons + 6 neutrons)</p>	<p><b>carbon-13</b></p> <p><sup>13</sup>C (6 protons + 7 neutrons)</p>	<p><b>carbon-14</b></p> <p><sup>14</sup>C (6 protons + 8 neutrons)</p>

[Fig. 5.5]

### The Bohr Atom [5.2]

- The atom as a miniature solar system
- But three special rules needed for Bohr Atom:
  - Electrons can only be in orbits at certain special radii.
  - Only one electron can be in a given orbit at one time.
  - Electron's energy stays constant while it is in orbit.
- Consequence of *quantum mechanics*.
  - Describes electrons as fuzzy probability distributions
    - not as discrete particles in discrete orbits
  - Too complicated! Bohr atom is almost right, so we'll use it

[pictures](#)

## Atomic Excitation

- Each Bohr orbit has its own distinct energy.
- For electron to move from inner orbit to one further out, it must gain exactly the energy difference between the orbits.
  - Can absorb photon with correct energy
  - Or can absorb kinetic energy through collisions.

[Fig. 5.8]

## De-Excitation

- For electron to fall back in towards nucleus, it must *lose* exactly the energy difference between the orbits.
  - Can *emit* photon with correct energy
  - Or can *lose* energy through kinetic energy carried off by collisions.

[Fig. 5.9]

## Ionization

- Very energetic photon  $\rightarrow$  electron acquires escape velocity.
    - Atom has same nucleus, but one less electron.
      - Atom is *ionized*.
    - Atom with all of its electrons is *neutral*. (neutral electrical charge)
  - Elements heavier than hydrogen start out with several electrons
    - $\rightarrow$  can be ionized several times
      - Example: oxygen  $^{16}\text{O}$ 
        - nucleus = 8 protons + 8 neutrons
        - $\text{O}^0$  or  $\text{O I}$  = nucleus with all 8 electrons.
        - $\text{O}^+$  or  $\text{O II}$  = nucleus with only 7 electrons.
        - $\text{O}^{++}$  or  $\text{O III}$  = nucleus with only 6 electrons.
- Each have completely different spectra.

## Recombination

- Ion recaptures a free electron  $\rightarrow$  photon is emitted.

3. The spectrum of the outer parts of a planetary nebula is very different from that of a black body because the planetary nebula is
  - a. very hot
  - b. very cool
  - c. not black
  - d. black
