

# Relativity

1905 - Albert Einstein:

- Brownian motion
  - atoms.
- Photoelectric effect.
  - Quantum Theory
- "On the Electrodynamics of Moving Bodies"
  - The Special Theory of Relativity

# The Luminiferous Ether

Hypothesis: EM waves (light) travel through some medium - The Ether

Speed of light:  $c = 3 \times 10^8 \text{ m/s}$   
w.r.t fixed ether.

The earth moves at  $v = 3 \times 10^4 \text{ m/s}$   
w.r.t fixed ether.

- Speed of light w.r.t earth should depend on direction.

# The Michelson-Morley Experiment

An interferometer

The interference fringes should shift.

But no effect was observed!

What was wrong?

## The Lorentz-Fitzgerald Contraction

Suppose that the ether squashes any object moving through it?

To counteract the change in light speed, we need:

$$d' = d \sqrt{1 - v^2/c^2}$$

# Galilean Transformations.

$$t' = t$$

$$z' = z$$

$$y' = y$$

$$x' = x - vt$$

# From Head on Collision to Collision at Rest by changing Frames

Start from known ("Obvious"):  
equal-mass head-on elastic collision

	Before	After
Known		
Unknown		

Figure 1.1

Relate to elastic collision with one at rest  
View train frame (5f/s right):  
transforms into known situation

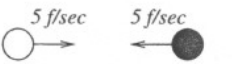

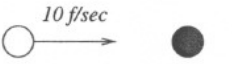

Train		
Station		

Figure 1.2

$$U_t = U_s - V \quad (+ u, v \text{ to right}): \quad U_t = U_s - 5$$

Then transform back to station (5f/s left):

$$U_s = U_t + V: \quad U'_s = U'_t + 5$$

Result: cue ball stops, target ball rolls on

## Equal-mass totally inelastic collision

	Before	After
<b>Known</b>		
<b>Unknown</b>		

Figure 1.3

Relate to inelastic collision with one at rest

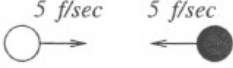

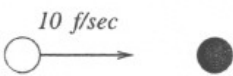

<b>Train</b>		
<b>Station</b>		

Figure 1.4

$$U_t = U_s - 5$$

$$U'_s = U'_t + 5$$

Result: combined mass moves at half speed of incident

## (Very) Asymmetric Elastic Collision

	Before	After
<b>Known</b>		
<b>Unknown</b>		?

Figure 1.5

Choose Train Frame to put big mass at rest:

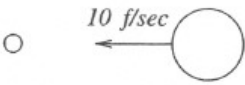

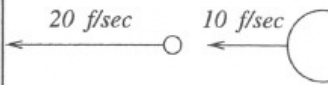

<b>Train</b>		
<b>Station</b>		

Figure 1.6

$$U_t = U_s - (-10) = U_s + 10$$

$$U'_s = U'_t - 10$$

Result: light ball (nearly) twice speed of heavy ball;  
heavy ball (nearly) unaffected

## Finally, use to solve for Asymmetric head-on Elastic Collision

Figure 1.7

Again Choose Train Frame to put big mass at rest:

$$U_t = U_s + 5$$

$$U'_s = U'_t - 5$$

Result: light ball (nearly) three times speed of heavy ball;  
heavy ball (nearly) unaffected

Example: drop tennis ball on top of basketball  
rebound matches this situation

Lessons from changing frames:

An exercise in Galilean transform for velocities

Analysis from the simplest point of view

Well-chosen transformation can give non-trivial results

In frame K, two charges at rest. Force is given by Coulomb's law.

In moving frame  $K'$ , two charges are moving.  
Since moving charges are currents,  
Force is Coulomb + Magnetism.

## Principle of relativity:

"The laws of nature are the same in all inertial reference frames"

## Something is wrong!

- Maxwell's Equations?
- The Principle of Relativity?
- Galilean Transformations?

Einstein decided

□ Galilean Transformations are the problem.

Einstein's two postulates:

1. The principle of relativity is correct.  
The laws of physics are the same in all inertial reference frames.
2. The speed of light in vacuum is the same in all inertial reference frames  
( $c = 3 \times 10^8$  m/s regardless of motion of the source or observer).

The second postulate seems to violate everyday common sense!

Rocket  
 $v = 0.5 c$

Light pulse  
 $v = c$

Observer

Einstein says: observer measures the light as traveling at speed  $c$ , not  $1.5c$ .

# Gedanken Experiments

A light clock:

It ticks every  $\Delta t = 2w/c$  seconds.  
One can synchronize ordinary clocks with it.

# Time Dilation

$O_G$ : Observer on Ground

$O_T$ : Observer on Truck

$O_T$ 's clock as seen from the ground:

$$c = 3 \times 10^8 \text{ m/s}$$

$$(ct/2)^2 - (vt/2)^2 = w^2$$

Time for one round trip of light, as seen from the ground:

$$t = (2 w/c) / \sqrt{1 - v^2/c^2}$$

For  $v = 0.6c$ ,  $t = (2 w/c) \times 1.25$

All of  $O_T$ 's processes slow down compared to  $O_G$  as seen by  $O_G$ .

Similarly,

All of  $O_G$ 's processes slow down compared to  $O_T$  as seen by  $O_T$ .

# Length Contraction

$O_G$ : Observer on Ground

$O_T$ : Observer on Truck

Device on truck makes mark on track each time clock ticks.

As seen from **ground**:

Distance between marks

$$= (\text{time between ticks}) \times v$$

$$= \left[ (2 w/c) / \sqrt{1 - v^2/c^2} \right] v$$

As seen from truck:

$$\begin{aligned}\text{Distance between marks} \\ &= (\text{time between ticks}) \times v \\ &= (2 w/c) v\end{aligned}$$

(To the person on the truck the time between ticks is  $(2 w/c)$ .)

$$\begin{aligned}(\text{Distance measured on truck}) \\ &= \sqrt{1 - v^2/c^2} \\ &\quad \times (\text{distance measured on ground})\end{aligned}$$

As seen from a moving frame, rest distances contract.

(L-F contraction)

# Simultaneity

Events occur at a well defined position and a time  $(x,y,z,t)$ .

But events that are simultaneous (same  $t$ ) in one inertial frame are not necessarily simultaneous in another frame.

The light from the two flashes reach  $O_G$  at the same time. He sees them as simultaneous.

$O_T$  passes  $O_G$  just as the lights flash.

But light from B reaches  $O_T$  first. Since both light beams started the same distance from her, and both travel at speed  $c$ , she concludes that B must have flashed before A.

# Lorentz Transformations

- Flashbulb at origin just as both axes are coincident.
- Wavefronts in both systems must be spherical:

$$x^2 + y^2 + z^2 = c^2 t^2 \quad \text{and}$$

$$x'^2 + y'^2 + z'^2 = c^2 t'^2$$

- Inconsistent with a Galilean transformation
- Also cannot assume  $t = t'$ .

Assuming:

- Principle of relativity
- linear transformation  $(x, y, z, t) \rightarrow (x', y', z', t')$

### Lorentz Transformations (section 2.4)

$$x' = \gamma (x - v t)$$

$$y' = y$$

$$z' = z$$

$$t' = \gamma (t - v x / c^2)$$

With

$$\gamma = 1 / \sqrt{1 - v^2/c^2} .$$

(Often also define  $\beta = v / c .$  )

# Time Dilation (again)

Proper time: time  $T_0$  measured between two events at the same position in an inertial frame.

$O_G$ 's clock:  $T_0 = t_2 - t_1$ ,  $(x_2 - x_1 = 0)$

$O_T$ 's clock:  $T' = t'_2 - t'_1$

$$t'_2 - t'_1 = \gamma(t_2 - t_1 - v/c^2(x_2 - x_1))$$

$$T' = \gamma T_0 > T_0$$

Clocks, as seen by observers moving at a relative velocity, run slow.

# Length Contraction (again)

Proper length: distance  $L_0$  between points that are at rest in an inertial frame.

$O_T$  on truck measures its length to be  $L_0 = x'_2 - x'_1$ . This is its proper length.  
 $O_G$  on ground measures its length to be  $L = x_2 - x_1$ , using a meter stick at rest ( $t_2 = t_1$ ).

Then

$$L_0 = x'_2 - x'_1 = \gamma(x_2 - x_1 - v(t_2 - t_1)) \\ = \gamma L$$

$O_G$  measures  $L = L_0 / \gamma < L_0$ .

Truck appears contracted to  $O_G$ .

# An application

Muon decays with the formula:

$$N = N_0 e^{-t/\tau}$$

$N_0$  = number of muons at time  $t=0$ .

$N$  = number of muons at time  $t$  seconds later.

$\tau = 2.19 \times 10^{-6}$  seconds is mean lifetime of muon.

Suppose 1000 muons start at top of mountain  $d=2000$  m high and travel at speed  $v=0.98c$  towards the ground. What is the expected number that reach earth?

Time to reach earth:

$$\begin{aligned} t &= d/v = 2000\text{m}/(0.98 \times 3 \times 10^8 \text{ m/s}) \\ &= 6.8 \times 10^{-6} \text{ s} \end{aligned}$$

Expect  $N = 1000 e^{-6.8/2.19} = 45$  muons.

But experimentally we see 540 muons!  
What did we do wrong?

Time dilation: The moving muon's internal clock runs slow. It has only gone through

$$\begin{aligned} t' &= 6.8 \times 10^{-6} \sqrt{1 - 0.98^2} \text{ s} \\ &= 1.35 \times 10^{-6} \text{ s} \end{aligned}$$

So  $N = 1000 e^{-1.35/2.19} = 540$  muons survive.

Alternate explanation: From muon's viewpoint, the mountain is contracted. Get same result.

# Addition of velocities

Galilean formula ( $u = u' + v$ ) is wrong.

Consider object, velocity  $u'$  as seen in frame of  $O_T$  who is on a truck moving with velocity  $v$  w.r.t the ground.

What is velocity  $u$  of the object as measured by  $O_G$  on the ground?

Recall  $u = \Delta x / \Delta t$ ,  $u' = \Delta x' / \Delta t'$ .

Inverse Lorentz transformation formulae:

$$\Delta x = \Delta ( \Delta x' + v \Delta t' )$$

$$\Delta t = \Delta ( \Delta t' + v \Delta x' / c^2 )$$

$$u = \frac{\Delta x}{\Delta t} = \frac{\Delta(\Delta x' + v \Delta t')}{\Delta(\Delta t' + v \Delta x' / c^2)}$$

$$u = \frac{u' + v}{1 + v u' / c^2}$$

For  $u'$  and  $v$  much less than  $c$ :

$$u \approx u' + v$$

Velocities in  $y$  and  $z$  directions are also modified (due to  $t' \neq t$ , see section 2.6)

Examples:

Rocket  
 $v = 0.5c$

Light pulse  
 $u' = c$

Observer

Observer sees light move at

$$u = \frac{0.5c + c}{1 + (0.5c)(c)/c^2} = c$$

Light moves at  $c = 3 \times 10^8 \text{ m/s}$  in all frames.

Rocket  
 $v = 0.8c$

Projectile  
 $u' = 0.5c$

Observer

Observer sees projectile move at

$$u = \frac{0.5c + 0.8c}{1 + (0.5)(0.8)} = 0.93c$$

Massive objects always move at speeds  $< c$ .

# The Twin Paradox

Suppose there are two twins, **Henry** and **Albert**. **Henry** takes a rocket ship, going near the speed of light, to a nearby star, and then returns. **Albert** stays at home on earth.

**Albert** says that **Henry**'s clocks are running slow, so that when **Henry** returns he will still be young, whereas **Albert** is an old man.

But **Henry** could just as well say that **Albert** is the one moving rapidly, so **Albert** should be younger after **Henry** returns!

Who is right?

The first scenario is the correct one.

The situation is not symmetric, because the rocket has to decelerate, turn around and accelerate again to return to earth. Thus, **Henry** is not in an inertial frame throughout the trip. He does return younger than **Albert**.

# Spacetime Diagrams: Minkowski

Put axes in same units:  
 $x$  in, say, light minutes or lightyears

© 2006 Brooks/Cole - Thomson

Slope higher for slower rocket, 45 degrees for light

(a)

© 2006 Brooks/Cole - Thomson

"Past" can get a signal to Present, but "Elsewhere" can't  
(light is too slow)

Present can affect future, but not "Elsewhere"

# The Twin Paradox: two inertial frames!

© 2006 Brooks/Cole - Thomson

$$v = .8 c, \gamma = 1/.6$$

$$\text{Frank: } T = 2 * 8\text{ly} / .8c = 2 * 10 = 20 \text{ y}$$

$$\text{Mary: } T = 2 * 10 \text{ y} / \gamma = 2 * 6\text{y} = 12 \text{ y}$$

# Relativistic Doppler Effect

Light source and observer approach each other with relative velocity,  $v$ .  
Light is emitted at frequency  $\nu_0$ .

Observer sees light at a higher frequency:

$$\nu = \frac{\sqrt{1 + \beta}}{\sqrt{1 - \beta}} \nu_0 \quad \text{with } \beta = v/c$$

- If source is receding, the formula still holds but now  $\beta$  is negative.

We know that the universe is expanding, because light from distance galaxies is red-shifted, indicating motion away from us.

## Comparison of Relativistic and NR Doppler Effect:

Relativistic (for light), source moving at  $\beta$

$$\nu = \nu_0 \sqrt{\{ (1+\beta) / (1-\beta) \}} = \nu_0 (1-\beta^2)^{1/2} / (1-\beta)$$

multiply top and bottom by  $(1-\beta)$

Nonrelativistic (for light,  $u=c$ , source moving at  $\beta$ )

$$\nu = \nu_0 \times 1 / (1 - \beta)$$

They agree whenever  $\beta$  is small  
same lowest order shift—from denominator  
numerator is higher order correction:

$$(1-\beta^2)^{1/2} \sim 1 - \frac{1}{2} \beta^2 \sim 1 \text{ for } \beta \ll 1$$

Remark:  $c = \lambda \nu$  Always, both NR and Rel:  
It's fundamental to mathematics of waves.

# Relativistic Momentum

Requirement: momentum is conserved in all inertial frames.

Assume:  $\vec{p} = m \vec{v}$ .

Elastic scattering in c-o-m frame:

Transform to frame of A:

It doesn't work!

Relativistic momentum:

$$\vec{p} = \gamma m \vec{v} = \frac{m\vec{v}}{\sqrt{1-v^2/c^2}}$$

Relativistic Kinetic Energy:

$$\begin{aligned} K &= (\gamma - 1) mc^2 \\ &= \left( \frac{1}{\sqrt{1-v^2/c^2}} - 1 \right) mc^2 \end{aligned}$$

For small velocities,  $v/c \ll 1$ :

$$\begin{aligned} K &= \left( 1 + \frac{1}{2} (v/c)^2 + \dots - 1 \right) mc^2 \\ &\approx \frac{1}{2} m v^2 \end{aligned}$$

For large velocities  $v \rightarrow c$ :

$$K \rightarrow$$

Massive objects always travel at speeds less than  $c$ .

## KE and velocity: Relativistic vs. Classical

© 2006 Brooks/Cole - Thomson

Noticeable departures for  $v/c > .4$  or so

Starting from  $v=0$ , takes infinite KE to get to  $v=c$

Velocity nearly stops changing after  $KE \sim 4 mc^2$

© 2006 Brooks/Cole - Thomson

$$KE = (\gamma - 1) mc^2$$

$\gamma = 2$  ( $KE = \text{rest}$ ) happens for  $\beta = \sqrt{1 - 1/\gamma^2} = .87$

electron has  $mc^2 = .511 \text{ MeV}$

# Relativistic Energy

According to Einstein, even a mass at rest has energy:

$$E_0 = m c^2 \quad (\text{rest energy})$$

Thus, the total energy of a moving object is

$$\begin{aligned} E &= K + E_0 \\ &= (\gamma - 1) m c^2 + m c^2 \\ &= \gamma m c^2 \end{aligned}$$

It is straightforward to show:

$$E^2 - p^2 c^2 = m^2 c^4$$

For a massless particle (e.g. a photon):

$$E = |\vec{p}| c$$

In general

$$v = \frac{|\vec{p}| c^2}{E} = \frac{\gamma m v c^2}{\gamma m c^2}$$

For a massless particle this gives

$$v = c$$

Massless particles travel at the speed of light  $c$ .

## Conservation Laws and $E = mc^2$

	NR	Relativistic
Mass	Always	Elastic Only
Momentum	Always	Always
Energy	KE: Elastic Only	Always
After relativistic redefinitions		

**Trade Conservation of Mass (NR)**

**for Conservation of Relativistic Energy**

NR conservation of mass: just a very good approximation

$E = \gamma mc^2$  is a convention, though a very sensible one.

$$E = KE + E_{\text{rest}}, \quad E_{\text{rest}} = mc^2$$

The physics (the "real"  $E = mc^2$ ) is in

$$\Delta E = \Delta mc^2$$

Changes in energy show up as immeasurably tiny changes in mass, for everyday cases like heating up an object.

But: if you change mass more substantially,  
it releases a LOT of Energy: typically kinetic

Or: use lots of energy (inelastic relativistic collision)  
to create new particles (more mass, less KE)

## Collisions of equal masses

Calculate either initial KE, or final effective mass

Fixed target, moving projectile

NR result

$$k_0 = \frac{1}{2} m u^2$$

$$K_{cm} = 2 \times \frac{1}{2} m (u/2)^2 = k_0 / 2 \quad (\text{linear})$$

In cm:  $-u/2, u/2$  are velocities, momentum sums to 0

Relativistic result (let  $c = 1$ ...)

$$\begin{aligned} M^2 &= E_i^2 - p_i^2 & (= E_f^2 - p_f^2 \text{ since relativistic invariant}) \\ &= (e_i + m)^2 - p_i^2 &= e_i^2 - p_i^2 + 2 e_i m + m^2 \\ & & \text{Using } e_i^2 - p_i^2 = m^2 \end{aligned}$$

$$M^2 = 2 m (e_i + m)$$

$$M = 2m\{1 + k/2m\}^{1/2}$$

Using  $e_i = k + m$

NR:  $k \sim k_0 \ll 2m$ , so  $M = 2m$  as expected

Relativistic:  $KE_{cm} = M - 2m$  (conserve  $E$ , not  $KE$ )

Can swap this  $KE$  of initial  $2m$ , for less  $KE$ , more mass in final state

Highly Relativistic case: when  $k \gg 2m$ ,

$$M = \sqrt{2km}$$

So only grows as square root, not linearly in initial  $k$

Most of initial  $KE$  wasted in motion of compound cm object  $M$

If collide equal masses head on, no such waste!

Much more  $M$  for similar electricity bill

For  $k \gg m$ , for each mass:

$$M^2 = E_i^2 - p_i^2 = (2e_i)^2 - 0 \quad (p \text{ sums to } 0)$$

$$M = 2(k + m) \sim 2k \text{ (linear): use a collider!}$$

Examples: head on collision of proton on proton ( $m$ )

Tevatron (collider):  $k = 1000 m$  ;

$m = \text{proton mass} \sim 1 \text{ GeV} = 10^9 \text{ eV}$ , so  $k \sim 1 \text{ TeV} = 10^{12} \text{ eV}$

$$M = 2000 m$$

Up to 1000 pairs of proton/antiprotons could be produced

LHC (collider):  $k = 7000 m \sim 7 \text{ TeV}$

$$M = 14000 m$$

Examples of fixed target:

Highest Energy cosmic rays colliding on proton in nucleus of air atom

$$k = 10^{20} \text{ eV} = 10^{12} m \quad (\sim 10^8 \text{ higher than LHC beam})$$

$$M = \sqrt{2km} = m \sqrt{2 \times 10^{12}} \sim 10^6 m$$

Still  $\sim 10^2$  higher than LHC but nowhere near  $10^8$

1 LHC beam as fixed target

$$M = \sqrt{2km} = m \sqrt{14000} \sim 120 m \ll 14000 m$$
