## Motion of light rays in the neighborhood of a spherical mass

## Review

The Schwarzschild metric

$$
\begin{aligned}
\mathrm{c}^{2}(\mathrm{~d} \tau)^{2}=\Sigma(\mathrm{r}) & \mathrm{c}^{2}(\mathrm{dt})^{2}-(\mathrm{dr})^{2} / \Sigma(\mathrm{r}) \\
& -\mathrm{r}^{2}(\mathrm{~d} \theta)^{2}-\mathrm{r}^{2} \sin ^{2} \theta(\mathrm{~d} \varphi)^{2}
\end{aligned}
$$

$\Sigma(\mathrm{r})=1-2 \mathrm{GM} / \mathrm{c}^{2} \mathrm{r}=1-\mathrm{r}_{\mathrm{S}} \mathrm{r}$;
$\mathrm{r}_{\mathrm{S}}=$ Schwarzschild radius $=2 \mathrm{GM} / \mathrm{c}^{2}$

Geodesic equations for coordinates $\{t, r, \theta, \varphi\}$

$$
\begin{align*}
& \sum(\mathrm{r}) \mathrm{dt} / \mathrm{d} \tau=\mathrm{a}  \tag{1}\\
& \mathrm{r}^{2} \mathrm{~d} \varphi / \mathrm{d} \tau=\lambda  \tag{2}\\
& \theta=\pi / 2 \\
& (\mathrm{dr} / \mathrm{d} \tau)^{2}=\left[\mathrm{a}^{2}-\Sigma(\mathrm{r})\right] \mathrm{c}^{2}-\lambda^{2} \Sigma(\mathrm{r}) / \mathrm{r}^{2}
\end{align*}
$$

Now, light rays (wave packets or photons) travel on null geodesics. A null geodesic is a geodesic curve for which $d \tau=0$. Light travels on the light cone; in a locally inertial frame,

$$
\begin{aligned}
\mathrm{c}^{2}(\mathrm{~d} \tau)^{2} & =\mathrm{c}^{2}\left(\mathrm{dt} \mathrm{t}^{2}\right)^{2}-\left(\mathrm{d} \mathbf{x}^{\prime}\right)^{2} \\
& \left.=\mathrm{c}^{2}(\mathrm{dt})^{2}\right)^{2}-\mathrm{c}^{2}\left(\mathrm{dt} \mathrm{t}^{2}\right)^{2} \\
& \text { because for light, }\left|\mathrm{d} \mathbf{x}^{\prime}\right|=\mathrm{cdt} \\
& =0
\end{aligned}
$$

Se we want to start with equations (1) -- (4), and then take the limit $\mathrm{d} \tau \rightarrow 0$. But the limit is delicate because some quantities are singular.

## $\varphi$ and T

$\Sigma(\mathrm{r}) \mathrm{dt} / \mathrm{d} \tau=\mathrm{a} \quad \rightarrow \infty$ as $\mathrm{d} \tau \rightarrow 0$
$\mathrm{r}^{2} \mathrm{~d} \varphi / \mathrm{d} \tau=\lambda \quad \rightarrow \infty$ as $d \tau \rightarrow 0$
but

$$
\frac{\mathrm{r}^{2} \mathrm{~d} \varphi / \mathrm{d} \tau}{\Sigma(\mathrm{r}) \mathrm{dt} / \mathrm{d} \tau}=\frac{\mathrm{r}^{2} \mathrm{~d} \varphi}{\Sigma(\mathrm{r}) \mathrm{dt}}=\frac{\lambda}{\mathrm{a}}
$$

so $\lambda$ /a remains finite as $d \tau \rightarrow 0$
Units: $a$ is dimensionless; $\lambda \sim \mathrm{m}^{2} / \mathrm{s}$ Define $b=\lambda /(c a)\{$ units: $m$ \}.
Then the equations for $\mathrm{t}(\varphi)$ is

$$
\frac{\mathrm{dt}}{\mathrm{~d} \varphi}=\frac{\mathrm{ar}}{} \mathrm{r}^{2} \mathrm{r}^{2}(\mathrm{r})=\frac{\mathrm{r}^{2}}{\mathrm{bc} \sum(\mathrm{r})}
$$

and that equation would be used to analyze the time dependence.

## $\varphi$ and $r$

$(\mathrm{dr} / \mathrm{d} \tau)^{2}=\left[\mathrm{a}^{2}-\Sigma(\mathrm{r})\right] \mathrm{c}^{2}-\lambda^{2} \Sigma(\mathrm{r}) / \mathrm{r}^{2}$

$$
\frac{(\mathrm{dr} / \mathrm{d} \tau)^{2}}{(\mathrm{~d} \varphi / \mathrm{d} \tau)^{2}}=\frac{|\mathrm{dr}|^{2}}{|\mathrm{~d} \varphi|}=\frac{\left[\mathrm{a}^{2}-\Sigma(\mathrm{r})\right] \mathrm{c}^{2}-\lambda^{2} \Sigma(\mathrm{r}) / \mathrm{r}^{2}}{\left(\lambda / \mathrm{r}^{2}\right)^{2}}
$$

$(\mathrm{dr} / \mathrm{d} \varphi)^{2}=\mathrm{r}^{4}\left\{\frac{\mathrm{a}^{2} \mathrm{c}^{2}}{\lambda^{2}}-\frac{\sum \mathrm{c}^{2}}{\lambda^{2}}-\frac{\Sigma}{\mathrm{r}^{2}}\right\}$
Now take the limit $d \tau \rightarrow 0$;
$a^{2} c^{2} / \lambda^{2}=1 / b^{2}$ and $\lambda^{2} \rightarrow \infty$;
thus

$$
\Sigma=1-2 \mathrm{GM} / \mathrm{c}^{2} \mathrm{r}=1-\mathrm{r}_{\mathrm{S}} / \mathrm{r}
$$

$$
(d r / d \varphi)^{2}=r^{4} / b^{2}-r^{2}+r_{s} r
$$

where $r_{s}=2 G M / c^{2}$.
That equation would be used to analyze the trajectory, $r(\varphi)$ or $\varphi(r)$.

The null geodesics have
$(\mathrm{dr} / \mathrm{d} \varphi)^{2}=\mathrm{r}^{4} / \mathrm{b}^{2}-\mathrm{r}^{2}+\mathrm{r}_{\mathrm{s}} \mathrm{r}$ where $\mathrm{r}_{\mathrm{S}}=2 \mathrm{GM} / \mathrm{c}^{2}$. Solution for $\mathrm{M}=0$; i.e., if there is no gravity, no curvature

$$
(\mathrm{dr} / \mathrm{d} \varphi)^{2}=\mathrm{r}^{4} / \mathrm{b}^{2}-\mathrm{r}^{2}
$$

Let $\mathrm{u}=\mathrm{b} / \mathrm{r}$; or, $\mathrm{r}=\mathrm{b} / \mathrm{u}$.
Then

$$
\begin{gathered}
\left(\frac{d u}{d \phi}\right)^{2}=1-u^{2} \\
u^{2}+(d u / d \phi)^{2}=1
\end{gathered}
$$

The solution is $u=\sin \varphi$; that is, $\mathrm{b}=\mathrm{r} \sin \varphi$.

The result is a straight line with $\mathrm{y}=\mathrm{b}$.
When there is no gravity, no curvature, a light ray travels on a straight line.

From the diagram, note that $\mathrm{b}=$ the impact parameter.

Also,
$\mathrm{r}_{\mathrm{c}}=$ the distance of closest approach to $\mathrm{O}=\mathrm{b}$.

## Deflection of light by the sun

--- one of the three tests of general relativity proposed by Einstein.

Light from a distant star approaches the sun, with impact parameter $b>R_{\text {sol }}$. What will happen?

To solve:
$(\mathrm{dr} / \mathrm{d} \varphi)^{2}=\mathrm{r}^{4} / \mathrm{b}^{2}-\mathrm{r}^{2}+\mathrm{r}_{\mathrm{S}} \mathrm{r}$ where $\mathrm{r}_{\mathrm{S}}=2 \mathrm{GM} / \mathrm{c}^{2}$
This term is very small. We could solve the equation approximately by perturbation theory; but we'll just solve it numerically with a
computer program.
Various parameters
b = impact parameter /input/
$\mathrm{r}_{\mathrm{c}}=$ distance of closest approach /calculate/
$\delta=$ the deflection angle /output/
Note from the diagram, the angle $(\varphi)$ at $r=r_{c}$ is $\pi / 2+\delta / 2$.
At closest approach, $\mathrm{dr} / \mathrm{d} \varphi=0$; so $r_{c}$ is the solution of this equation

$$
r^{4} / b^{2}-r^{2}+r_{s} r=0
$$

Because $r_{s}$ is small, $r_{c} \approx b-r_{s} / 2$.
We'll need $r_{c} \leqq R_{\odot} ; r_{c}=R_{\odot}$ is called "grazing incidence.

## SOLAR PARAMETERS

In[277]:= Clear[Um, Us, Ukg]

Out[370]= 1.0000078762833193242247573812766

## integral

$\ln [377]=U m=1$
intgl $=$ NIntegrate $[1 / \operatorname{Sqrt}[r \wedge 4 / b \wedge 2-r \wedge 2+r 0 * r],\{r, r c$, Infinity $\}$, AccuracyGoal $\rightarrow 16$, PrecisionGoal $\rightarrow 16$, WorkingPrecision $\rightarrow 24$ ]

Out[377]= 1
Out[378]= 1.57080057419882043743099

## deflection $\delta$

$\ln [379]=\delta=-\mathrm{Pi}+2 *$ intg 1
secondsofarc $=\delta *(360 /(2 * P i)) * 3600$
Out[379] $=8.49480784763639934 \times 10^{-6}$
Out[380]= 1.752179894799035525

For grazing incidence, the deflection of light by the sun is 1.75 seconds of arc.

## Predicted by Einstein in 1917.

A famous expedition to observe stars behind the sun during a solar eclipse was supervised by Arthur Eddington, in 1919. He found that the observed positions of the stars were deflected toward the sun, just as predicted by Einstein's theory.

Arthur Eddington's photograph of 29 May, 1919, taken of a full solar eclipse. The apparent displacement of a known star just behind the sun had been attributed by Newton to the bending of light rays by the sun. Einstein's prediction of a visual displacement twice that of Newton's was attributed by Einstein to the sun's warping of space. This photograph proved Einstein's prediction more accurate, and his theory correct:
