

# Diffraction

- Diffraction occurs when a wave passes through a small opening not so different in size from the wavelength of the wave
- The wave spreads out as we saw previously
- So instead of a bright spot just in the middle we see a spread-out distribution of light
  - ◆ but with some structure to it
- Type of diffraction we're studying is called Fraunhofer diffraction
  - ◆ screen is far away from slit
  - ◆ ...or there's a converging lens just after the slit

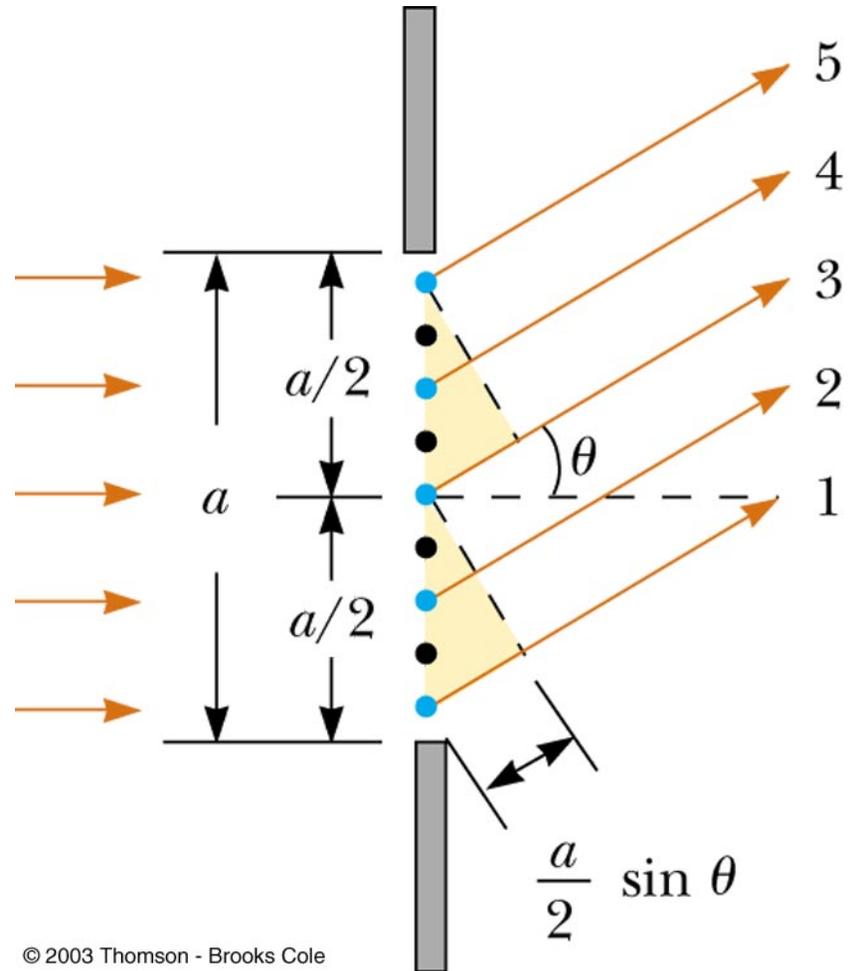

© 2003 Thomson - Brooks Cole (a)

→ Don't worry about the lens;  
Just think of the screen as far away

# Where are the dark spots?

- Here's where Huygen's principle comes in handy
- As the wave travels through the slit, treat each point in the slit as a source of waves
- Light from one part of the slit can interfere with light from another part
- Let's divide the slit into halves and consider the wavelets coming from point 1 and from point 3
- Wavelet 1 has to travel further
- IF the additional distance,  $a/2\sin\theta$  is equal to  $\lambda/2$ , then the wavelets from points 1 and 3 are exactly half of a wavelength out of phase
  - ◆ destructive interference
- Also true for 3 and 5, 2 and 4, any two points in the top and bottom of the slit separated by  $a/2$

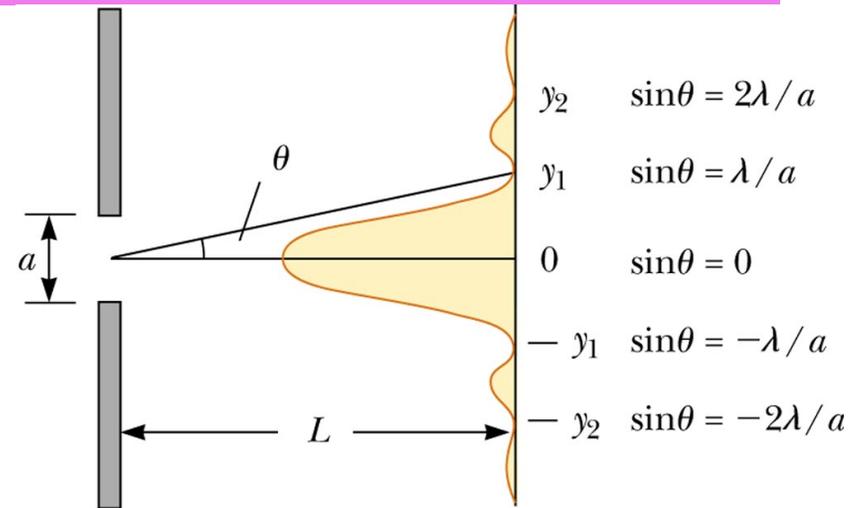

© 2003 Thomson - Brooks Cole

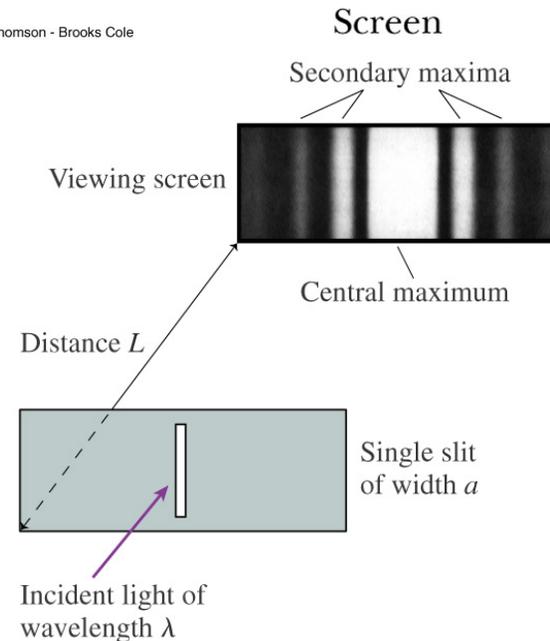

Can go through the same exercise dividing the screen in 4 parts, 6 parts,...

# Dark spots

- So dark spots when
  - ◆  $a/2 \sin\theta = \lambda/2$
  - ◆ ...or  $a/2 \sin\theta = 2\lambda/2$
  - ◆ ...or  $a/2 \sin\theta = 3\lambda/2$
- Corresponding to
  - ◆  $\sin\theta_1 = \lambda/a$
  - ◆  $\sin\theta_2 = 2\lambda/a$
  - ◆  $\sin\theta_3 = 3\lambda/a$
  - ◆  $\sin\theta_m = m\lambda/a$
  - ◆ Everything is in phase at  $\theta=0$ , so there's a bright spot there
  - ◆ and other bright spots roughly half-way between the dark spots

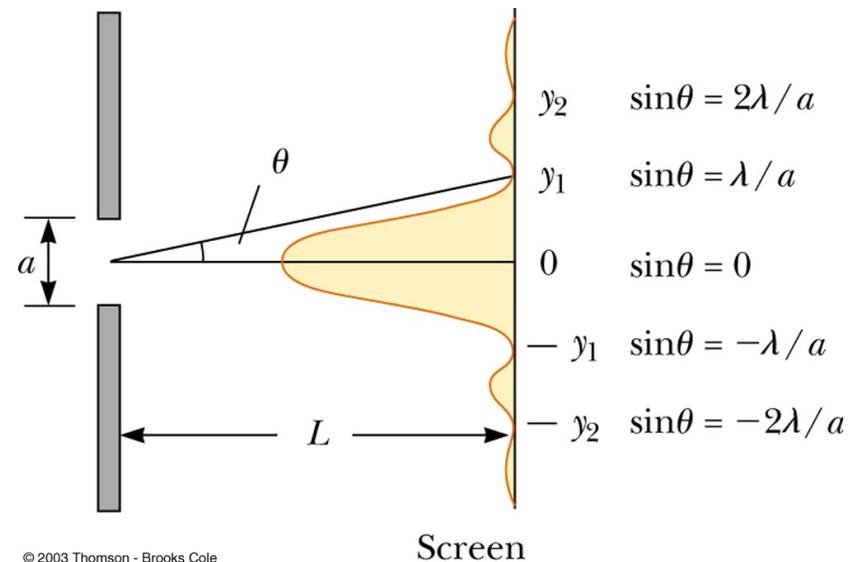

© 2003 Thomson - Brooks Cole

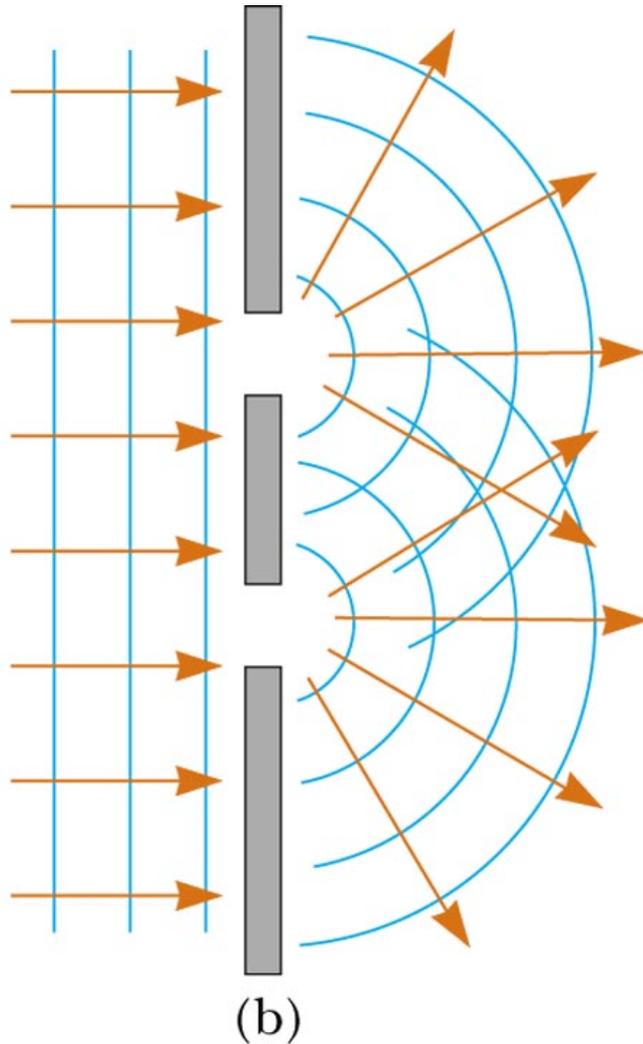

# Example

- You need to use your cellphone, which broadcasts an 800 Mhz signal, but you're behind two massive radio-absorbing buildings that only have a 15 m space between them
- What is the angular width, in degrees, of the electromagnetic wave after it emerges from between the buildings

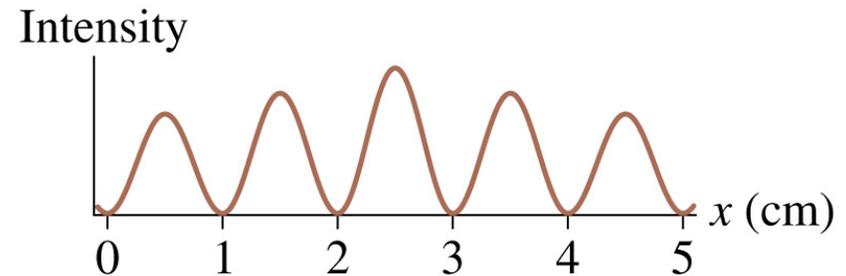

# Back to 2 slits

- When I shine coherent light through two narrow slits, I see BOTH diffraction and interference
- I see the overall diffraction pattern with the interference fringes inside

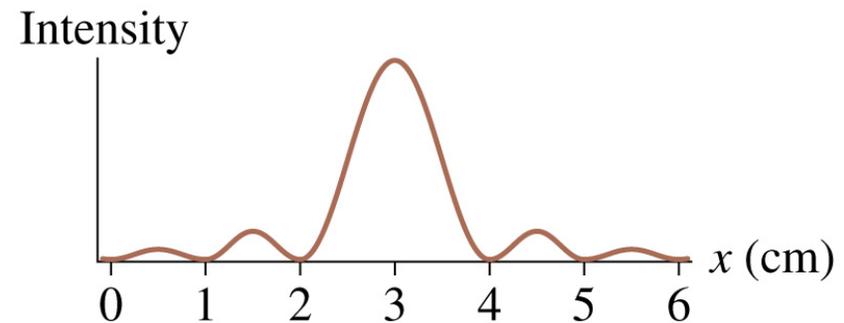

# Example

- Is the intensity pattern shown to the right produced by a single or double slit?
- If single slit, what is the width of the slit?
- If double slit, what is the spacing between the slits?
  - ◆ assume 1 m to the screen and 500 nm wavelength light

# Example

- Is the intensity pattern shown to the right produced by a single or double slit?
- If single slit, what is the width of the slit?
- If double slit, what is the spacing between the slits?
  - ◆ assume 1 m to screen and 500 nm wavelength

---

A laboratory experiment produces a single-slit diffraction pattern on a screen. If the slit is made narrower, the bright fringes will be

- A. Closer together.
- B. In the same positions.
- C. Farther apart.
- D. There will be no fringes because the conditions for diffraction won't be satisfied.

# Diffraction grating: Let's go crazy and put in lots of slits

Light diffracts through each of the slits

A device like this is called a diffraction grating but there's both diffraction and interference taking place

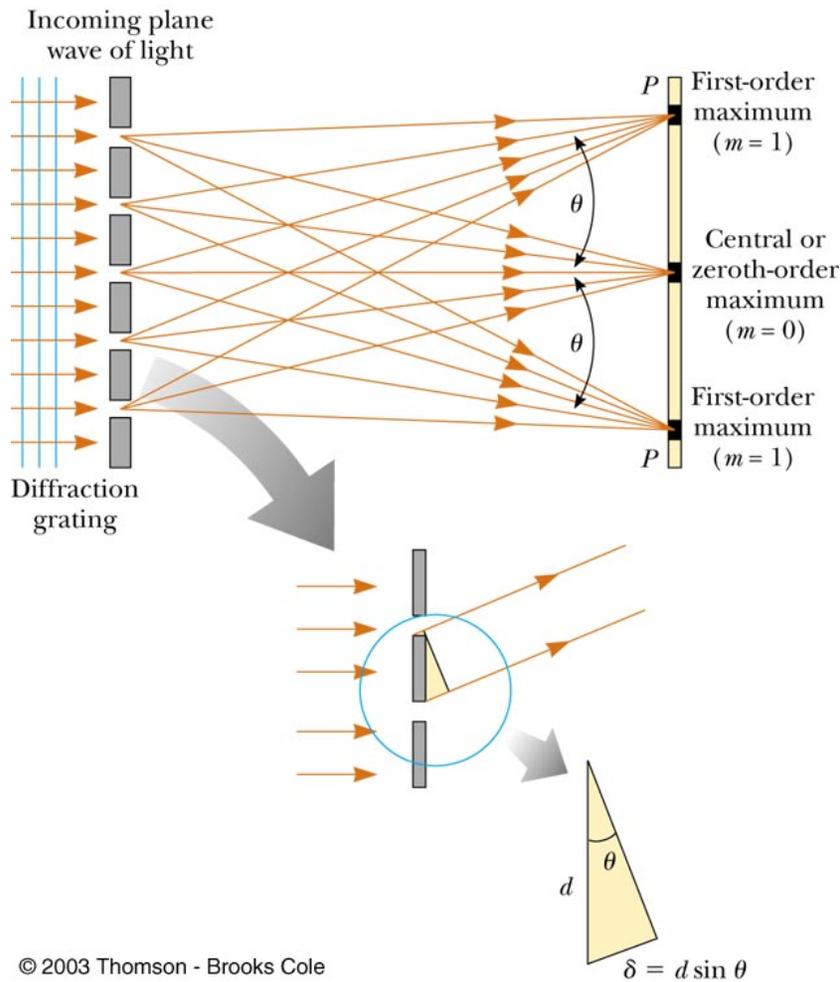

and we get interference between each of the diffracted waves

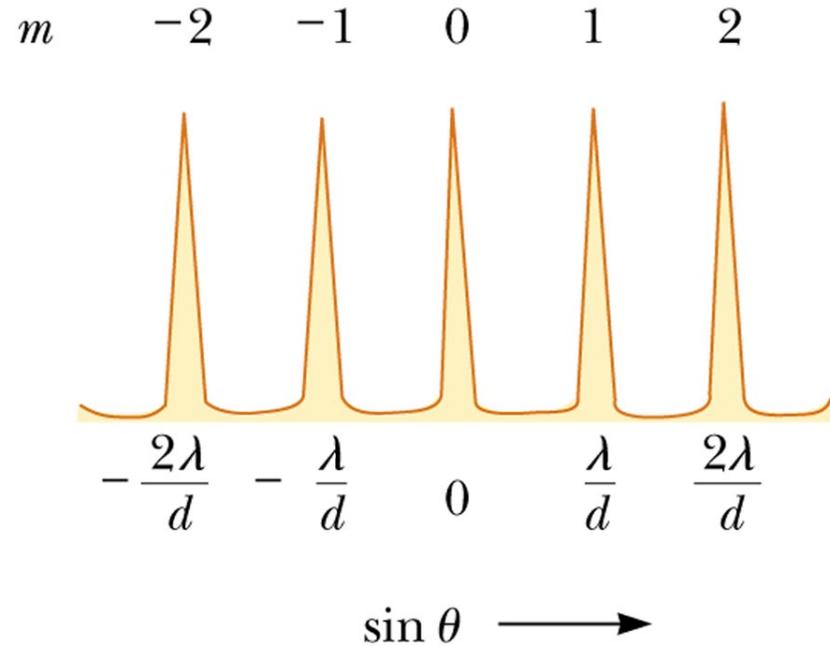

Again, there's a path length difference between light passing through different slits  
bright lines or spots when  $d \sin \theta_{\text{bright}} = m\lambda$   
 $m=0,1,2,\dots$

# Intensity pattern

© 2003 Thomson - Brooks Cole

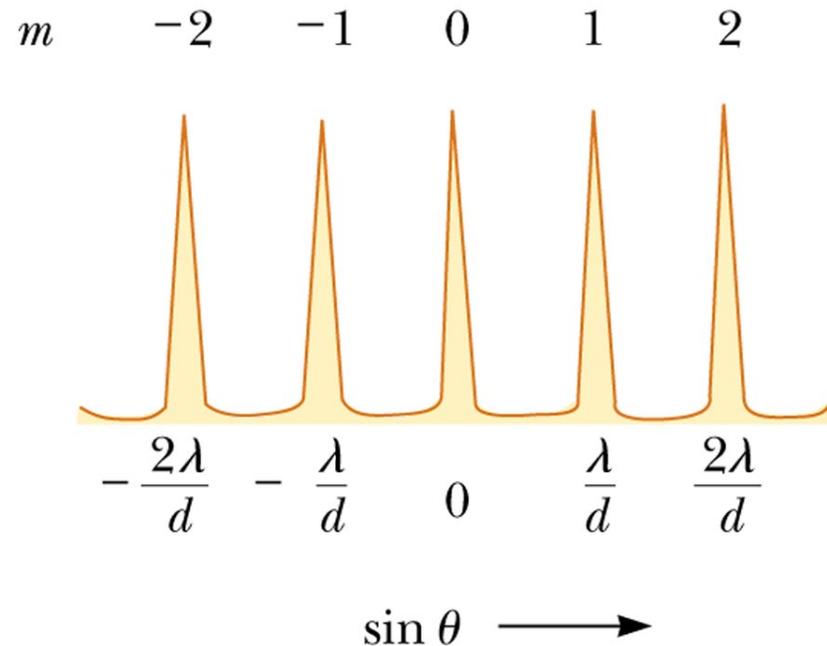

© 2003 Thomson - Brooks Cole

The more slits in the grating the sharper are the interference peaks;  
 Can also make a diffraction grating by having finely etched lines on a reflective surface

# Diffraction gratings

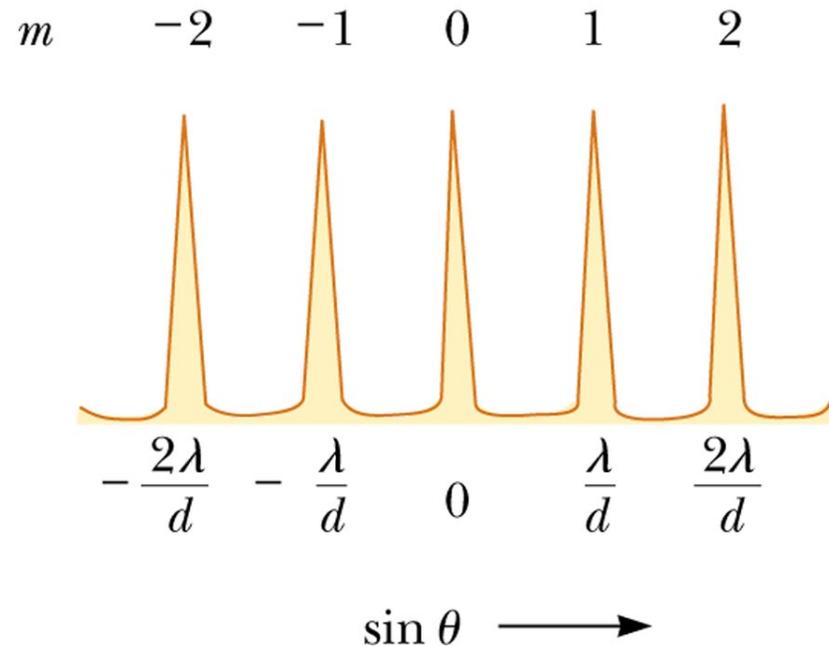

- If there were no interference whatsoever, the average intensity across the screen would just be  $N I_0$ , where  $I_0$  is the average intensity for just one slit
- Energy must be conserved so if there is zero intensity in regions of destructive interference, the intensity in the regions of the maxima must be greater
- At the principle maxima, the electric and/or magnetic fields from the waves coming from each of the slits add coherently
  - ◆  $E_{\max} = N E_0$
  - ◆  $I_{\max} = N^2 I_0$
  - ◆ thus, for 2 slits,  $I_{\max} = 4 I_0$

© 2003 Thomson - Brooks Cole

# Diffraction gratings

- If the maximum energy increases markedly for N slits, then the space over which the maximum occurs ( $\Delta\theta$ ) must be much smaller in order to conserve energy
- Roughly,
 
$$I_{\max} \Delta\theta \approx NI_o$$
- Solving this equation
 
$$\Delta\theta = \frac{NI_o}{I_{\max}} = \frac{NI_o}{N^2 I_o} = \frac{1}{N}$$
- As N increases, it is less likely to have total constructive interference; path-length difference between adjacent slits has to be an integral multiple of the wavelength
- So, as N increases
  - ◆ the height of the principle maxima increases as  $N^2$
  - ◆ the width decreases as  $1/N$
  - ◆ the maxima are spaced further apart

# Diffraction gratings

- There are two types of spectra
  - ◆ hot luminous objects such as the sun emit a continuous spectrum
  - ◆ light emitted by gas discharge tube contain only discrete, individual wavelengths
- Every element in the periodic table has its own unique spectrum
  - ◆ atomic spectra can serve as fingerprint for elements
  - ◆ you'll see this in PHY192L/PHY252

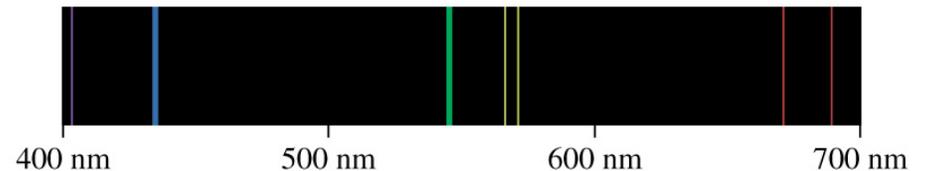

(a) Incandescent light bulb

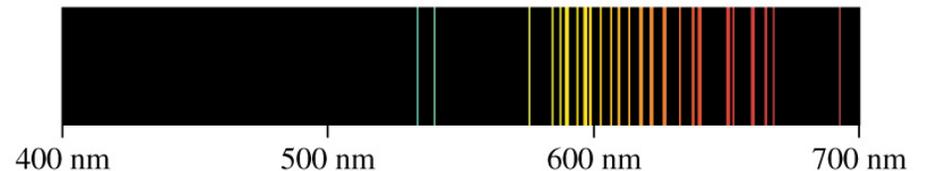

(b) Helium

(c) Mercury

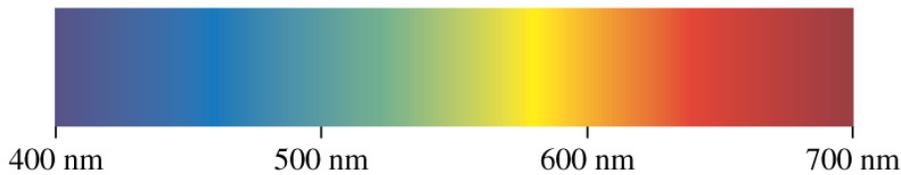

(d) Neon

# Diffraction gratings

- This makes diffraction gratings very useful, since tall narrow peaks can be easily seen and measured.
